

Core Switch URL

Overview

In this article, I discussed about different ways of implementing URL rewriting in ASP.NET Core. I also explained the importance of URL rewriting and different status codes that has to be used with URL redirect. I hope you will find this a. In this article, I discussed about different ways of implementing URL rewriting in ASP.NET Core. I also explained the importance of URL rewriting and different status codes that has to be used with URL redirect. I hope you will find this article helpful. If you have any suggestions, then please feel free to ask into the comment section. URL rewriting is a process of modifying current request URL and pointing it to some other URL to complete the request. If you were creating an application that has pages /about-us and /teams but later after analyzing the site structure, you got a suggestion to move /teams page under /about-us so URL looks like /about-us/teams. After changing struct. There may be various situations where you need URL rewriting in your application. Just an example, if SSL is installed for an application, then it can be accessed using both HTTP and HTTPS protocols. In both protocols, request goes for the same page, but SEO identifies them as separate page. Hence, you need URL rewriting to avoid duplicate tracking. In the URL rewrite, client sees different URL in browser and server processed different URL. So, basically what we can say is, URL rewrite modifies the URL into server-side before it is fully processed. And this modified URL is not seen to the user's browser. User only sees what they have requested. Redirect is a process of sending a new request on. In this section, I will explain different ways of URL rewriting middleware with code example. I am not going to discuss about how to create new project in Visual Studio. If you are not familiar with creating project in Visual Studio then you can follow this tutorial. All the code example I have included in this section is based on Visual Studio 202.
